Health Care

Background

Postoperative nausea and vomiting (PONV) is a common, unpleasant, and potentially dangerous complication of surgery. It is often ranked as the anesthetic complication patients most wish to avoid. Nevertheless, PONV afflicts 30 to 50 percent of all surgical patients. Risk screening is imperfect and has remained relatively unchanged since the late 20th century. Improving PONV screening would allow for better targeted administration of antiemetic therapy. Based on research literature that suggests nausea and vomiting may be affected by oxygen level, the aim of this project was to determine if intraoperative arterial oxygen content level (CaO₂) is associated with PONV.

A retrospective observational research study was completed at Providence Sacred Heart Medical Center (PSHMC).

- Included patients \geq 18 years old who received general anesthesia from 2015-2019, and who were extubated prior to leaving the operating suite.
- Project was approved by the PSHMC CIRC and deemed exempt by the IRB.
- An a priori power analysis indicated the need for a sample size of 4,322 patients to achieve 80 percent power.
- De-identified patient data was securely extracted and stored in a HIPAA compliant REDCap project database.
- Hemoglobin (Hgb) was deemed usable if extracted within 14 days of surgery.
- CaO_2 was determined by the truncated formula, Hgb*SpO₂*1.34.
- The PONV outcome was determined by nursing documentation of PONV or administration of antiemetic medication in the postoperative period.
- Descriptive analyses were conducted to examine baseline demographics and incidence of PONV.
- Bivariate and multivariable analysis of event rates at various CaO₂ levels with risk and odds ratio were calculated.

Intraoperative Arterial Oxygen Content and Postoperative Nausea and Vomiting

observational research, a relationship between CaO₂ and / was observed. Overall PONV rates were consistent with the rch literature. Analysis demonstrated that CaO₂ below 16 mL was associated with increased PONV in all time intervals ared with physiologically normal CaO₂. Hemoglobin level was negatively correlated with PONV. In an adjusted model, the ased odds of PONV among patients with sub-physiologic CaO₂ comparable to commonly accepted PONV risk factors.

own confounding variables limit the utility of observational rch to inform treatment decisions. However, analyzing the ciation of CaO₂ with PONV is not suited to experimental inquiry. spective studies reproduce the findings of this research in a t of subjects demographically comparable to surgical patients rally, anesthesia providers should begin to use estimates of perative CaO₂ to help guide antiemetic administration practice.
